VDJ rearrangement

An example schema for TCR β locus

Variable, Diversity and Joining are chosen at random, V-D and D-J junctions are filled with non-template N bases.

VDJ rearrangement

An example schema for TCR β locus

Variable, Diversity and Joining are chosen at random, V-D and D-J junctions are filled with non-template N bases.

VDJ rearrangement mechanism can be efficiently recaptured with a probabilistic model [Murugan et al. PNAS 2012]

$$\begin{aligned} P(\sigma) &= P(V)P(D, J) \\ &\times P(\#del_V|V)P(\#del_J|J)P(\#del_{D5}, \#del_{D3}|D) \\ &\times P(\#ins_{VD})P(\#ins_{DJ}) \prod_{i \in ins_{VD}} P(b_i|b_{i-1}) \prod_{i \in ins_{DJ}} P(b_i|b_{i+1}) \end{aligned}$$

TCR regions

A TCR chains consists of the following regions:

In total there are four framework (FRs) and three complementarity determining regions/loops (CDRs).

TCR regions

A TCR chains consists of the following regions:

In total there are four framework (FRs) and three complementarity determining regions/loops (CDRs).

The likely functions of these regions are:

- ▶ FR regions maintain TCR secondary structure and (possibly) play role in MHC binding
- ▶ CDR1,2 are germline encoded and play role in antigen recognition, as well as (possibly) MHC binding
- ▶ CDR3 plays a major role in antigen recognition and is extremely variable

TCR repertoire sequencing

An example of a RepSeq dataset

After all pre-processing steps:

- ▶ Read grooming (filtering, etc)
- ▶ UMI-based assembly (for molecular barcoded data)
- ▶ V-D-J mapping and clonotype assembly

An example of a RepSeq dataset

After all pre-processing steps:

- ▶ Read grooming (filtering, etc)
- ▶ UMI-based assembly (for molecular barcoded data)
- ▶ V-D-J mapping and clonotype assembly

We finally get clonotype frequency tables that look like

Index	Frequency	Count	CDR3AA	V	D	J	CDR3NT
1	1.0%	3913	CSA GG L G STDTQYF	TRBV20-1	TRBD1	TRBJ2-3	TGCAGT GCTG GGGGGC TCGGTAGCACAGATACGCAGTATTTT

The assignment

Downloading data

Navigate to `https://github.com/antigenomics/repseq-forensics-tutorial` and download the data + code bundle as zip

The screenshot shows the GitHub repository page for `antigenomics / repseq-forensics-tutorial`. The repository is described as "RepSeq data mining basics in R". It has 7 commits, 1 branch, 0 releases, 1 contributor, and is licensed under CC-BY-SA-4.0. The "Clone or download" button is highlighted with a red circle. Below the repository information, a table lists the files in the repository:

File	Description	Last Commit
<code>datasets</code>	Shuffle datasets, add PDF	12 hours ago
<code>slides</code>	Slides WIP	10 hours ago
<code>.gitignore</code>	Slides WIP	10 hours ago
<code>LICENSE</code>	Add license	13 hours ago

Executing R code

Open the tutorial1.Rmd in RStudio, it can be found in the root folder of the bundle.

```
108 Plot diversity values
109
110 ~~~{r message=FALSE}
111 diversity %>%
112   melt %>%
113   # set what values we are going to plot
114   # fct_reorder reorders sample id by value
115   ggplot(aes(x=fct_reorder2(sample_id, variable, value), y=value)) +
116   # we'll make a bar plot
117   geom_bar(stat = "identity", fill = "#0570b0") +
118   # show each index on different subplot
119   facet_wrap(~variable, scales = "free_y", ncol = 1) +
120   xlab("") + ylab("Diversity index") +
121   theme_bw()
122 ~~~
```

Executing R code

```
108 Plot diversity values
109
110 ```{r message=FALSE}
111 diversity %>%
112   melt %>%
113   # set what values we are going to plot
114   # fct_reorder reorders sample id by value
115   ggplot(aes(x=fct_reorder2(sample_id, variable, value), y=value)) +
116   # we'll make a bar plot
117   geom_bar(stat = "identity", fill = "#0570b0") +
118   # show each index on different subplot
119   facet_wrap(~variable, scales = "free_y", ncol = 1) +
120   xlab("") + ylab("Diversity index") +
121   theme_bw()
122 ```

The assignment

The assignment

Using the analysis results we've obtained we need to assign feature labels to each sample. Namely, you need to fill the table with the following structure:

sample	donor	subset	phenotype	CMVstatus
s1	D1	CD4	memory	CMV-
s2	D2		naive	CMV+
s3	D1	CD8	naive	CMV-
...

Details

Table filling rules:

- ▶ Column names should match those on previous slide
- ▶ Sample id should be one of $s_1..s_{16}$
- ▶ Two distinct donor IDs should be used, naming doesn't matter
- ▶ Subset should be either **CD4** or **CD8**
- ▶ Phenotype should be either **memory** or **naive**
- ▶ CMV status should be either **CMV+** or **CMV-**
- ▶ Unknown/ambiguous fields should be left blank

A hint

While you can unambiguously assign CD4/8 and memory/naive labels, as well as point out biological replicates of the same sample, assigning donor labels is tricky.

First, it is impossible to link CD4-CD8 cells of the same donor. Same for CMV status, that is unambiguous only for CD8+ memory T-cells. Therefore I expect that you mark donors in the way they will distinguish samples/replicas coming from the same and different donors.

I.e. there is no problem if donor labels are swapped between CD4 and CD8 T-cells as far as they point to distinct donors for CD4 or CD8 T-cells coming from different donor.

Feedback

Send me filled tables as plain text tab-delimited files, the file name should be in format `your-name.assignment.txt`

Thanks for your attention!

These slides and a PDF file containing compiled analysis results can be found in `slides/` and `root` folders of the data and code bundle.
